

CS344: Design and Analysis of Computer Algorithms

Homework 2

Group Members: Stephen Kuo, Derek Mui

1.11) Is $4^{1536} - 9^{4824}$ divisible by 35?

Answer:

$$4^{1536} = (4^3)^{512} = 64^{512} = (35 + 29)^{512}$$

Since 35 is divisible by 35, we can continue with 29^{512}

$$29^{512} = (29^2)^{256} = 841^{256} = (840 + 1)^{256}$$

Since 840 is divisible by 35, we are left with $1^{256} \bmod 35$

$$9^{4824} = (9^2)^{2412} = 81^{2412} = (70 + 11)^{2412}$$

Since 70 is divisible by 35, we can continue with 11^{2412}

$$(11^3)^{804} = 1331^{804} = (1330 + 1)^{804}$$

Since 1330 is divisible by 35, we are left with $1^{804} \bmod 35$

$$(1^{256} \bmod 35) - (1^{804} \bmod 35) = 0 \text{ Thus, yes it is divisible by 35}$$

1.12) What is $2^{2^{2006}} \bmod 3$

Answer:

$$2^{2^{2006}} = 4^{2^{2006}} = 4^{2^{1003}} = 16^{1003} = (15 + 1)^{1003}$$

We know 15 is divisible by 3, so that leaves us with 1^{1003} .

Thus, the answer is 1

1.13) Is the difference of $5^{30,000}$ and $6^{123,456}$ a multiple of 31?

Answer:

$$5^{30000} = 5^{3^P 10000} = 125^{10000} = (124 + 1)^{10000}$$

Since 124 is divisible by 31, we are left with $1^{10000} \bmod 31$

$$6^{123456} = 6^{2^6 1728} = 36^{61728} = (31 + 5)^{61728}$$

Since 31 is divisible by 31, we are left with 5^{61728}

$$5^{61728} = 5^{3^{20576}} = 125^{20576} = (124 + 1)^{20576}$$

Since 124 is divisible by 31, that leaves us with 1^{20576}

$$(1^{10000} \bmod 31) - (1^{20576} \bmod 31) = 0$$

Thus, yes, the difference is a multiple of 31

1.25) calculate $2^{125} \bmod 127$ using any method you choose

Answer:

$$2^{125} = (2^{119} * 2^6) = (2^{7^{17}} * 2^6) = (128^{17} * 2^6) = (127 + 1)^{17} * 2^6$$

Because 127 is divisible by 127, that leaves us with $1^{17} * 2^6$

$$1^{17} * 2^6 = 1 * 2^6 = 64$$

Thus, the answer is 64

1.33) Give an efficient algorithm to compute the least common multiple of two n-bit numbers x and y, that is, the smallest number divisible by both x and y. What is the running time of your algorithm as a function of n?

Answer:

temp

1.39) Give a polynomial-time algorithm for computing $a^{b^c} \bmod p$, given a, b, c, and prime p.

Answer:

temp

Problem)

Answer:

temp
